# Chapter 1

## Lecture 1: Introduction

Taught in collaboration with MSR Redmond for the Q# bits.

Topics:

- Intro: Transition from Classical to Quantum: Stern Gerlach, Sequential Stern Gerlach, Rise of randomness.
- Foundations of Quantum Theory: States, Ensembles, Qubits, Pure and Mixed states, Multi qubit states, Tensor products, Unitary transforms, Spectral decomposition, SVD, Generalized measurements, Projective measurements, POVM, Evolution of quantum state, Krauss Representation.
- Quantum Entropy: Subadditivity of Entropy, Avani-Licb(?) Inequality, Quantum channel, Quantum channel capacity, Data compression, Benjamin Schumahir(?) theorem.
- Quantum Entanglement: EPR paradox, Schmidt decomposition, Purification of entanglement, Entanglement separability problem, Pure and mixed entangled states, Measures of Entanglement.
- Quantum information processing protocols: Teleportation, Superdense coding, Entanglement swapping.
- Impossible operations in quantum information theory: No cloning, No deleting, No partial erasure.
- Quantum Computation: Introduction to Quantum Computing, Pauli gates, Hadamard gates, Universal gates, Quantum algorithms (Shor, Grover search, machine learning and optimisation).
- Quantum programming: Programming quantum algorithms, Q# programming language, quantum subroutines.

Books:

- Quantum computation and Quantum information — Nielsen and Chuang.

- Preskill lecture notes.

Grading:

- Possibility of open book take-home open ended exam for the finals.
- Mid 1: 15%
- Mid 2: 15%
- End sem (open book?) : 30%
- Assignments: 15%
- Projects: 25%

## 1.1 Stern-Gerlach: A brief, morally correct construction of qubits

light rays  $\rightarrow [z] \rightarrow (z+, z-) \rightarrow \text{block } (z-) \rightarrow [x] \rightarrow (x+, x-) \rightarrow \text{block } (x-) \rightarrow [z] \rightarrow (z+, z-?)$

$[z]$  represents a polarizer along that axis.

- Since we first polarized along  $z$ , how did we manage to get out light rays in the  $x$  direction? The polarization should have killed everything.
- Since we blocked  $z-$ , How did we get back  $z-$  after passing stuff through  $[x]$ ? Something has changed drastically from our classical picture.

We can consider  $|z+\rangle$  to be something like:

$$|z+\rangle \equiv \frac{1}{2}|x+\rangle + \frac{1}{2}|x-\rangle$$

Where  $|x+\rangle$  and  $|x-\rangle$  are basis vectors for some vector space over  $\mathbb{R}$ .

If we were to pass the  $z+$  light rays through  $[y]$ , then we would get  $|y+\rangle, |y-\rangle$ . So,  $|z+\rangle$  is also:

$$|z+\rangle \equiv \frac{1}{2}|y+\rangle + \frac{1}{2}|y-\rangle$$

### 1.1.1 Analogy with polarization of light

Consider a monochromatic light wave in the  $z$  direction. A linearly polarized light with polarization in the  $x$  direction which we call  $x$  polarized light is given by:

$$E_x = E_0 \hat{x} \cos(kz - \omega t)$$

$\omega \equiv \text{frequency} \equiv ck$ ,  $c \equiv \text{speed of light}$ ,  $k \equiv \text{wave number}$ .

Similarly,  $y$  polarized light is given by:

$$E_y = E_0 \hat{y} \cos(kz - \omega t)$$

Consider the case where we have  $x$  filters along direction  $-$ ,  $x'$  filter along direction  $/$ ,  $y$  filters along direction  $|$ . In this case, we can have  $x, x', y$  filters arranged sequentially give us non-zero output (contrast with just having  $x, y$ ).

We can express the  $x'$  polarization as:

$$E_0 \hat{x}' \cos(kz - \omega t) = \frac{E_0}{\sqrt{2}} \hat{x} \cos(kz - \omega t) + \frac{E_0}{\sqrt{2}} \hat{y} \cos(kz - \omega t)$$

By analogy, we write:

$$|z_+\rangle \equiv \frac{1}{\sqrt{2}} |x_+\rangle + \frac{1}{\sqrt{2}} |x_-\rangle$$

However, we now have probability  $\frac{1}{\sqrt{2}}$ , but we want  $\frac{1}{2}$ . So, we define the probability as:

$$\langle x_+ | x_- \rangle^2 = \frac{1}{2}$$

$z_+ \equiv x$  polarization

$z_- \equiv y$  polarization

$x_+ \equiv x'$  polarization

$x_- \equiv y'$  polarization

This problem can be solved again by polarization of light. This time, we consider circularly polarized light which can be obtained by letting linearly polarized light passing through a quarter wave plate (?)

When we pass such circularly polarized light through an  $x$  or  $y$  filter, we again obtain either an  $x$  polarized beam, or a  $y$  polarized beam of equal intensity. Yet, everybody knows that circularly polarized light is totally different from  $45^\circ$  linearly polarized light.

A right circularly polarized light is a linear combination of  $x$  polarized light and  $y$  polarized light, where the oscillation of the electric field for the  $y$  component is  $90^\circ$  out of phase with the  $x$  polarized component.

$$E = \frac{E_0}{\sqrt{2}} \hat{x} \cos(kz - \omega t) + \frac{E_0}{\sqrt{2}} \hat{y} \cos\left(kz - \omega t + \frac{\pi}{2}\right)$$

$$\frac{E}{E_0} = \frac{1}{\sqrt{2}} \hat{x} e^{i(kz - \omega t)} + \frac{i}{\sqrt{2}} \hat{y} e^{i(kz - \omega t)}$$

Similarly, left circularly polarized light is:

$$E = \frac{E_0}{\sqrt{2}} \hat{x} \cos(kz - \omega t) - \frac{E_0}{\sqrt{2}} \hat{y} \cos\left(kz - \omega t + \frac{\pi}{2}\right)$$

## 1.2 Observable

An observable is something that we observe.

$$Z|z+\rangle = \frac{\hbar}{\sqrt{2}}|z+\rangle \quad Z|z-\rangle = \frac{\hbar}{\sqrt{2}}|z-\rangle$$
